Getting Started with InsuranceSuite Administration

This overview includes information that administrators can use to learn more about the concepts, processes, and tasks that keep the system secure, fast, and reliable.

Administering security in InsuranceSuite

The system uses roles and permissions to control what users can see and do. See *InsuranceSuite Security Administration* for information on how to protect data and manage access. For example, it provides information on the following tasks:

- **Managing users:** Update passwords for default users and change the unrestricted user if necessary.
- **Managing secure communications:** Configure encryption for data sent between the browser and the server.
- **Securing access to InsuranceSuite application objects:** Assign system permissions to roles and map these roles to specific business items.
- **Securing access to notes and documents:** Create security types and access profiles to protect sensitive files.
- **Securing access to claims and exposures in ClaimCenter:** Map claim access types to permissions and build access control levels for sensitive claims.

Administering InsuranceSuite servers

Administrators manage the application servers to ensure the software runs smoothly for all users. See *InsuranceSuite Server Administration* for information such as how to complete the following:

- **InsuranceSuite server configuration:** Define server roles and set environment properties.
- **InsuranceSuite application server administration:** Start or stop the application server, monitor server performance, manage event messages, and tune server caching.
- **Server tools:** Use **Server Tools** screen in the InsuranceSuite application to manage various aspects of a running an InsuranceSuite application server, such as to track batch processes, work queues, and log levels.
- **External server configuration:** Use substitution parameters to modify server properties at run-time and store sensitive information securely.
- **InsuranceSuite application clusters:** Manage server instances, monitor cluster health, and handle component lease failovers.

- **InsuranceSuite application process management:** Manage the processing of batch items in work queues and batch processes.

Administering InsuranceSuite databases

The database stores all the information for the application. See *InsuranceSuite Database Administration* for information on how to complete tasks such as:

- **Database configuration:** Set up database connection pools and configure settings for upgrades.
- **Database maintenance:** Run consistency checks, update database statistics, and purge unwanted data to maintain performance.
- **Importing and exporting administrative data:** Use XML or CSV files to import or export administrative data, such as security zone data, proxy users data, or ICD codes.

Administering business rules in InsuranceSuite

In PolicyCenter and ClaimCenter, business rules allow the system to perform actions automatically based on specific events. See *InsuranceSuite Business Rules Administration* for information on how to complete tasks such as:

- **Administering business rules:** Create, edit, and deploy rules to manage activities or underwriting issues.
- **Business rules import and export:** Move rule versions between development, testing, and production environments.

Using system and internal tools in InsuranceSuite

System and internal tools help administrators fix problems and monitor the system's health. See *InsuranceSuite System and Internal Tools* to determine which tool to use. For example:

- Use **Internal Tools** to reload configuration files and adjust the testing system clock during the development phase.
- Use **System Tools** to execute command-line utilities to ping servers, verify configurations, and manage user sessions.
